

Lamport total ordering

18 Final

sequence entering :-

P2, P1, P3

Final

Token Ring Algorithm

→ Process must be in ordered and
Ring arrangement

Step-1 :- process 0 gets the token initially

Step-2 :- The token is passed around the
ring

Step-3 :- if a process need to access a
shared resource it waits for token to
arrive

Step-4 :- after getting the token it execute
critical section and release resource

Step-5 :- pass the token to next process
if next process donot want to enter
cs, it also pass the token

Issue of Token Ring:-

(1) Lost Token

Issue of Richard Agarwal (Decentralized)

(1) Deadlock

(2) Less fault tolerance

Solution :- Voting

if a process P_i receive a "Retract message"

from Process P_j and has not entered its critical section, it sends P_j a "Relinquish message"

and that vote no longer counts.

Q : memory coherence protocols:-

mechanism that controls / synchronizes accesses is needed to maintain memory coherence

- ① sequential consistency
- ② General consistency
- ③ processor consistency
- ④ weak consistency
- ⑤ Release consistency

Q (Final)

Q : memory coherence Protocol

- ① write - Invalidate protocol
- ② write - update protocol

what is thrashing? Final

→ Thrashing refers to situation which occurs when there is Mismatch between the rate of data production and the capacity of the system to handle or process that data.

what is Indirect Communication? Final

Communication between entities in distributed system through an intermediary and no direct coupling between sender and receiver

key properties

- ① space uncoupling
- ② Time uncoupling

Space uncoupling

18 Final

refers to key properties indirect communication where ^{sender} donot need to know and identify receivers, sender/receiver can be replaced, updated, Replicated or migrated

Time uncoupling

Sender and receiver donot have to exists at the same time

Time coupled and space coupled

communication directed towards a given receiver where receiver must exist at that ~~time~~ moment in time

message passing, Remote Invocation

space uncoupled
and Time uncoupled

(18 Fin 1)

→ Sender doesn't need to know the identity of receiver

→ Sender and receiver can have independent lifetime.

Communication
paradigm

:- Indirect communication

① pub-sub system

② message queue

③ Distributed shared memory

④ Group communication

(18 Fin 1)

Multicast
communication

:- communication based on a sender and a group of receiver

Ex:- Group communication

Q Briefly explain pub-sub system. Give a proper diagram and example [16 Final]

pub → publisher :- publish structural event

sub → subscriber :- express interest in particular published event

(subscription)

pub-sub system :- matches subscription against published events by delivery event notification

Applications
that can use
pub-sub
system

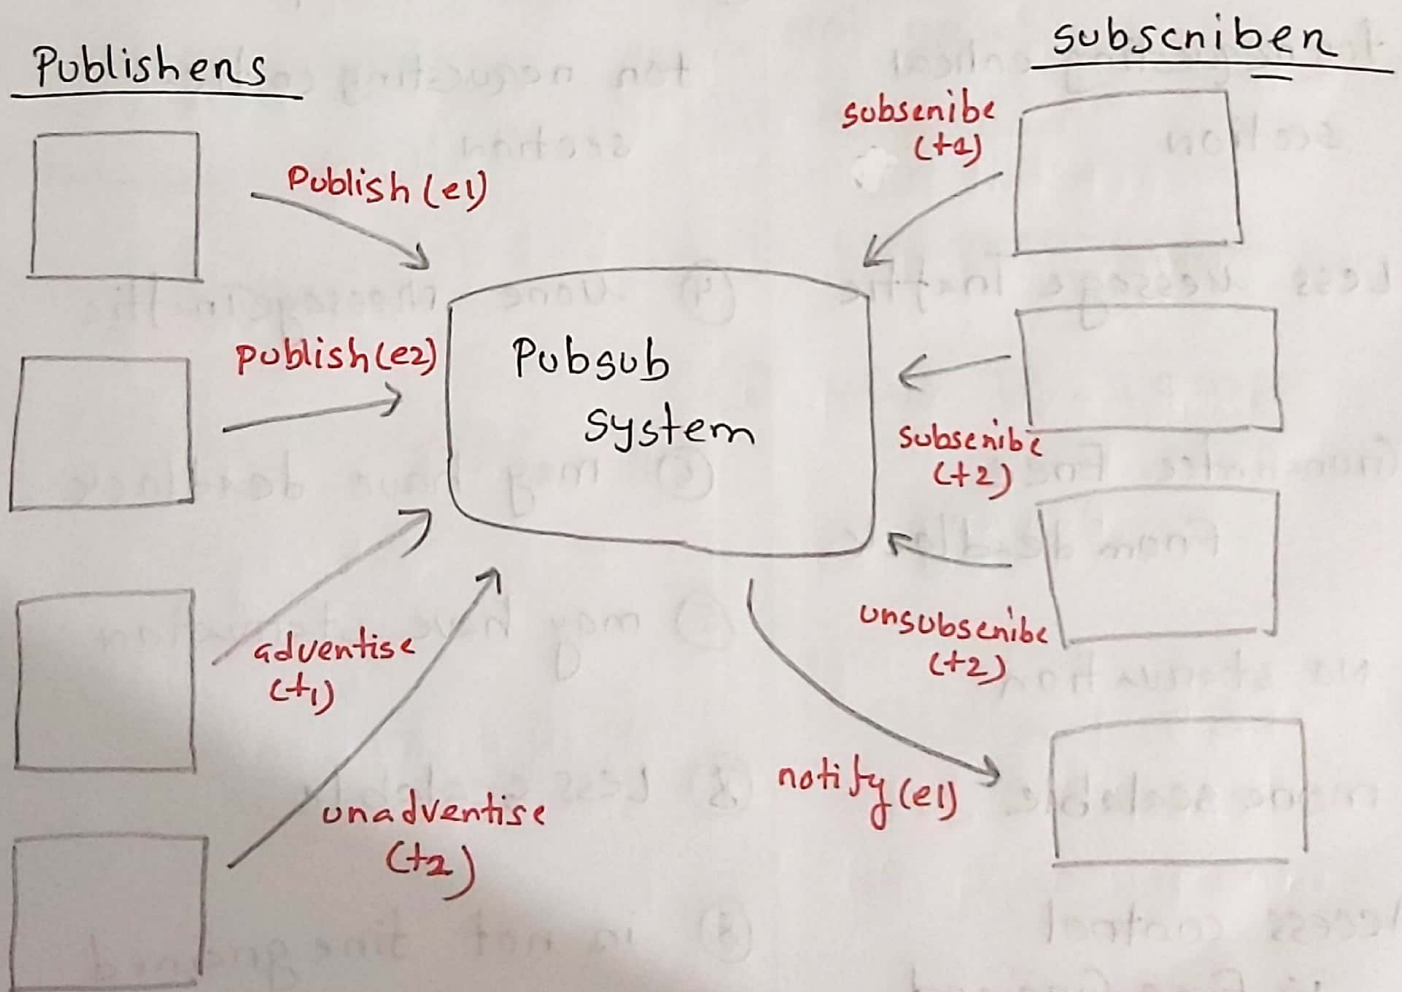

[18 Final]

- ① Financial system
- ② Live Feeds including RSS or RDF
- ③ Ubiquitous computing support
- ④ Monitoring Application

→ heterogeneous + Asynchronous

pub-subsystem operations

- ① publish → publish an event by publisher
- ② subscribe → subscribe to a particular pattern
- ③ notify → event arrives at subscriber
- ④ unsubscribe → to revoke subscription
- ⑤ advertise → declare nature of future event
- ⑥ unadvertise → revoke an advertisement

Token based solution

Final
16

- ① A unique token is shared among all process
- ② To enter critical section, process must have token
- ③ use sequence order for requesting critical section
- ④ Less message traffic
- ⑤ Guarantee free from deadlock
- ⑥ No starvation
- ⑦ more scalable
- ⑧ Access control is Fine Grained

Permission based solution

- ① There is no concept of token
- ② To enter critical section need permission of other processes
- ③ use Timestamp order for requesting critical section
- ④ more message traffic
- ⑤ may have deadlock
- ⑥ may have starvation
- ⑦ Less scalable
- ⑧ is not fine grained

connection Oriented

- ① Designed for Telephone system
- ② need end to end connection between sender and receiver before transmission
- ③ needs authentication
- ④ Higher Bandwidth
- ⑤ more Reliable
- ⑥ No congestion
- ⑦ Higher overhead
- ⑧ TCP :- Example

Final

Connectionless

- ① Designed for postal system
- ② transfer data packets between sender to receiver without creating any connection
- ③ no needs authentication
- ④ Less Bandwidth
- ⑤ Not reliable
- ⑥ congestion
- ⑦ Less overhead
- ⑧ UDP, IP, ICMP

TCP

Transmission Control Protocol

① requires established connection before transmitting data

② sequence data and send in a specific order

③ Retransmit data if packets fail to arrive

④ Guarantee delivery

⑤ check for errors in data arrival

UDP

User Datagram Protocol

① no connection is needed for data transfer

② cannot arrange / sequence data

③ No data retransmitting
Lost data cannot retrieve

④ do not Guarantee delivery

⑤ do not check all errors

⑥ do not support
broadcasting

⑥ support broad
casting

⑦ speed slow
but
complete delivery data

⑦ Fast
but
risk of incomplete
data delivery

⑧ best For

- Email or texting
- File transfer
- web browsing
- transferring files
(family photo)

ensure data arrives
exactly it was sent

→ pre-recorded

Streaming NETFLIX
HBO

⑧

- Live streaming
- Online gaming
- video chat / conference
- speed data transfer
(lag free gaming)

→ multicasting

→ VoIP (in app voice
calling)

→ Domain system
Name IP addressing

→ less packet loss

→ large Range than TCP

18 Final

what is Map Reduce ?

→ perform processing
the large data in 10^5 s
and parallel manner

The term Map reduce actually refers to the following different tasks that Hadoop program do

- ① The Map Task :- This is the first task which takes input data and converts it into a set of data which individual elements are broken down into tuple key / value pairs
- ② The Reduce Task :- This task takes output from a map task as input and combines those data tuples into a smaller set of tuples. The Reduce task is always performed after map task

How does Map Reduce works?

18 Final

① Input partitioning

② Map phase

→ assigned to different map

→ Map (key, value)

↓
word

↓
occurrence

③ shuffling and sorting

→ group same key value pair

④ Reduce phase

→ Reduce function receives all pairs with the same key

→ Reduce (key, list(value))

→ list (output)

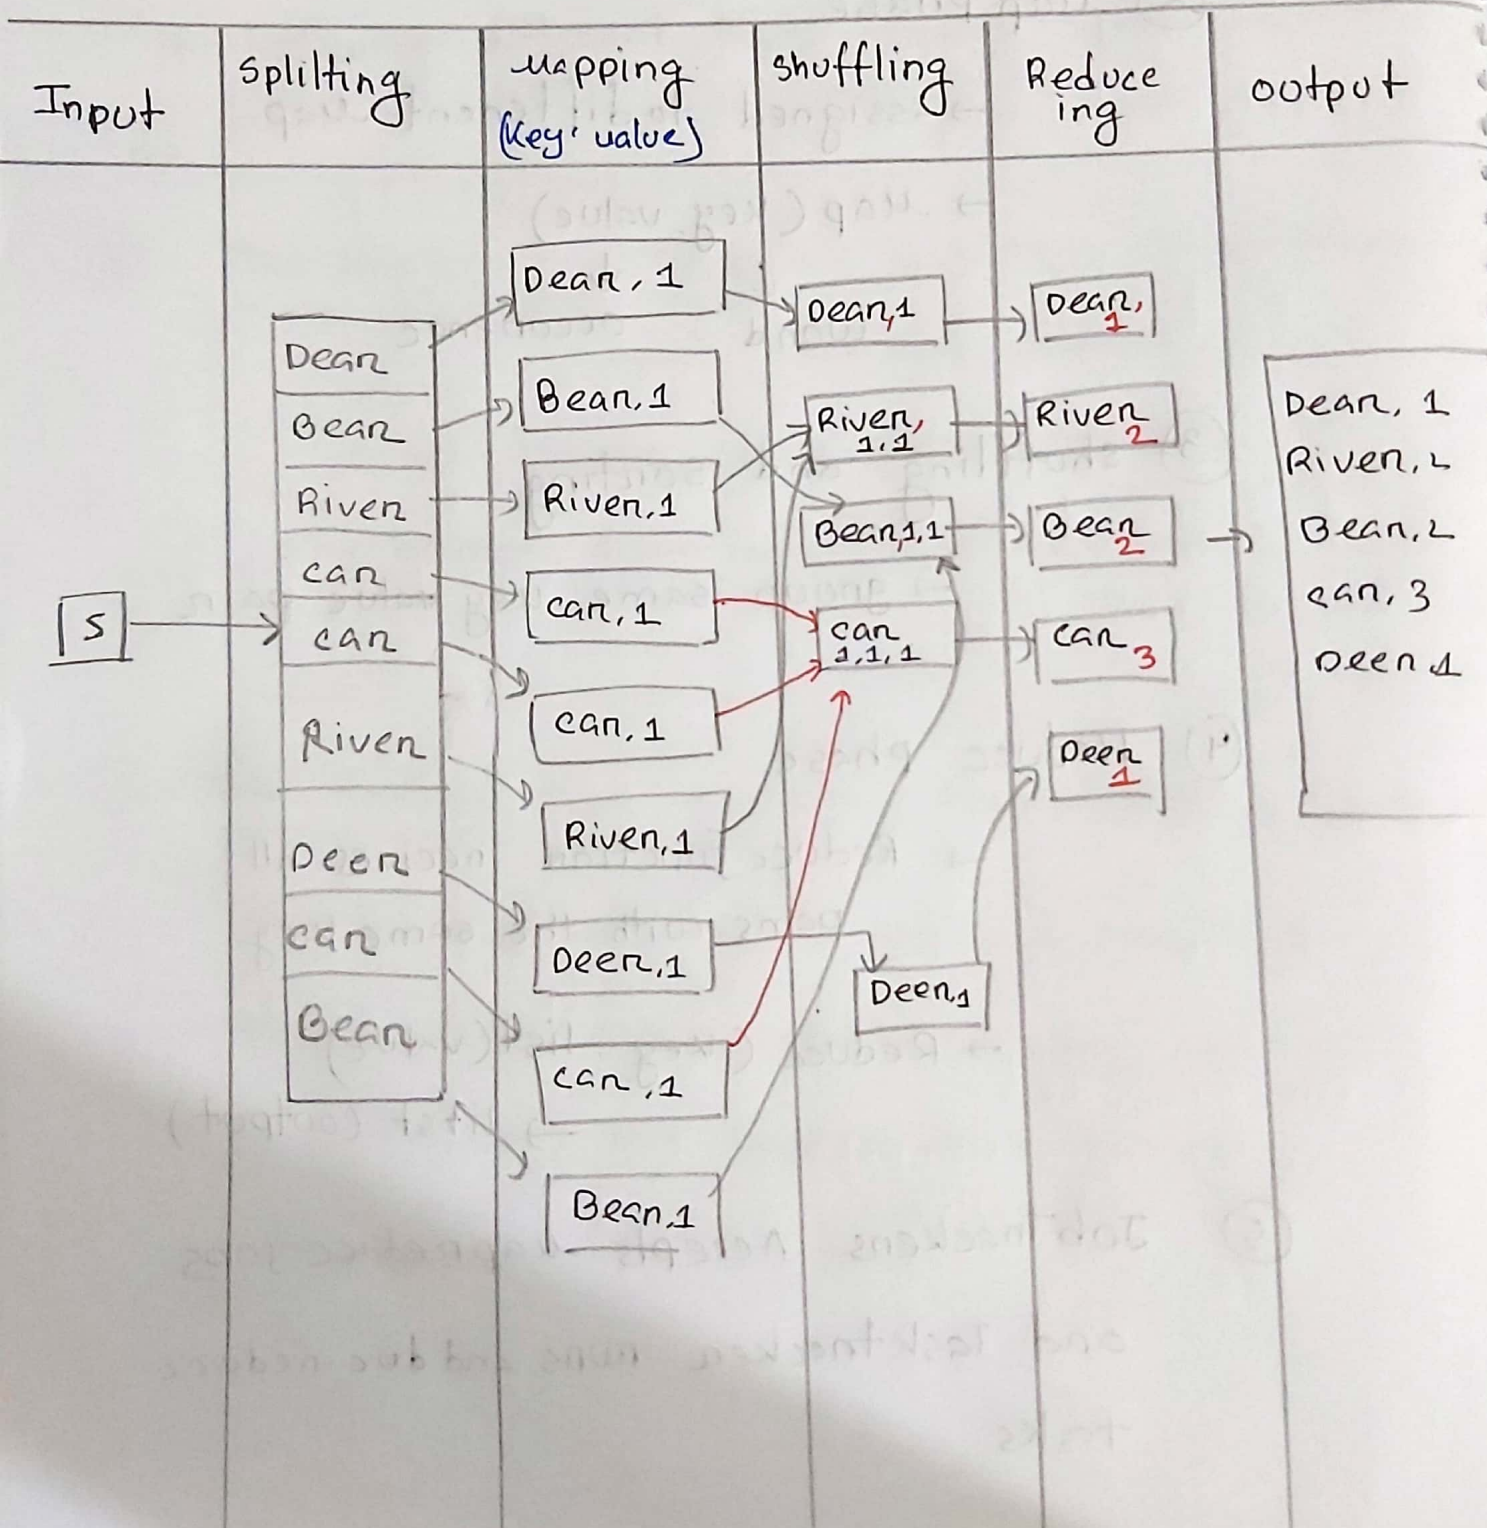

⑤ Jobtrackers Accepts mapreduce jobs and Tasktrackers runs and reduce tasks

18/11
Final

→ convert the occurrence using Map Reduce

Q Following words

S = "Deen, Bear, River, can, can, River, Deen
can, Bear"

18/16
Final what does Hadoop do?

Hadoop is an essential framework that allows distributed processing of large datasets across clusters of computers using a simple programming model.

includes

① MapReduce : divides application into many small blocks of work

② HDFS :- (Hadoop distributed File system)

creates multiples replicas of data blocks for reliability, placing them on compute nodes around cluster
